

Technical standard for interoperable telemetry, revision 4. Section 2.1 defines the Frame Checkpoint. Every Frame carries a Sequence Number and a Frame Type. A Collector validates the Frame Checkpoint before accepting a Frame. The Frame Type determines which Payload Schema applies. Rejected Frames are counted by the Rejection Counter.

Section 3.2 specifies transport. The Telemetry Gateway forwards Frames over the Message Bus. The Message Bus guarantees at-least-once delivery. Duplicate Frames are discarded by the Deduplication Window. The Retention Policy governs how long the Archive keeps a Frame. Operators tune the Deduplication Window and the Retention Policy independently.

Section 5 addresses conformance. A Conformance Suite exercises the Collector against the Reference Vectors. Any Device failing the Reference Vectors fails conformance. The Audit Log records every rejection emitted by the Frame Checkpoint. Certification bodies publish the Audit Log annually.
